

PERFORMANCE-BASED REGULATION

Aligning utility incentives with policy objectives and customer benefits

A 21st Century Electricity System Issue Brief

By Advanced Energy Economy

September 2017

ABOUT ADVANCED ENERGY ECONOMY

Advanced Energy Economy (AEE) is a national association of businesses and business leaders who are making the global energy system more secure, clean and affordable. Advanced energy encompasses a broad range of products and services that constitute the best available technologies for meeting energy needs today and tomorrow. AEE's mission is to transform public policy to enable rapid growth of advanced energy businesses. AEE and its State Partner organizations are active in 26 states across the country, representing roughly 1,000 companies and organizations in the advanced energy industry. Visit www.aee.net for more information.

ABOUT THIS ISSUE BRIEF

The U.S. utility sector has entered a period of foundational change not seen since the restructuring of the late 1990s. Change is being driven by new technologies, evolving customer needs and desires, environmental imperatives, and an increased focus on grid resiliency. With these developments come challenges, but also new opportunities to create an energy system that meets the changing expectations of consumers and society for the coming decades. We call this the *21st Century Electricity System*: a high-performing, customer-focused electricity system that is efficient, flexible, resilient, reliable, affordable, safe, secure, and clean. A successful transition to a 21st Century Electricity System requires careful consideration of a range of interrelated issues that will ultimately redefine the regulatory framework and utility business model while creating new opportunities for third-party providers and customers to contribute to the operation of the electricity system.

To support this transition, Advanced Energy Economy (AEE) has prepared several issue briefs that are intended to be a resource for regulators, policymakers, and other interested parties as they tackle issues arising in the rapidly evolving electric power regulatory and business landscape.¹ This issue brief on **Performance-Based Regulation (PBR)** describes this emerging regulatory approach, provides various performance incentive design options, and lays out recommended steps to follow to implement PBR.²

SUMMARY

Performance-based regulation (PBR) is a regulatory framework designed to better align the financial interests and actions of regulated utilities with public interest objectives and consumer benefits. A PBR framework rewards utilities for achieving well-defined outcomes (performance metrics) as opposed to simply incentivizing capital investment (inputs), which is the primary driver today of utility revenue and profits. Regulatory reforms, such as PBR, have the potential to change how utilities, customers and third-party providers generate, deliver, and use energy.

AEE believes that PBR, in its various forms, can serve as a foundational regulatory framework

of the electric grid of the future. Future infrastructure investments must be evaluated in light of technological innovations, and judged on the basis of the value delivered by and through those investments. In this regard, AEE supports regulatory mechanisms that enable value creation, long-term viability of the utility business model, and deployment of the modern technologies that will form the basis of a 21st century power grid. In support of these goals, this issue brief lays out the basic concept of performance-based regulation, considers different performance incentive design options, and offers implementation recommendations.

INDUSTRY & REGULATORY EVOLUTION

The U.S. utility sector is in a period of significant change, driven largely by information technology and falling costs for distributed energy resources (DER).³ At the same time, U.S. electric investor-owned utilities continue to invest on the order of \$100 billion annually, as aging infrastructure is replaced and modernized.⁴ Those investments must be consistent with the evolving needs of customers and must be guided by regulators to ensure long-term compatibility with the grid of the future.

The energy infrastructure and markets of the future will be more complex, will include a greater number and variety of actors, and will present technical challenges (such as managing two-way power flows over the electricity distribution system and a much larger number of interconnected devices) as well as business challenges (such as the long-term viability of a utility business model now built around increasing capital deployment and rising energy sales). With these developments come challenges, but also new opportunities. If managed successfully, these changes present opportunities for greater

customer choices and engagement, the creation of a more efficient and resilient energy system, and opportunities for utilities to embrace new business concepts that will sustain them in the decades to come.

AEE views new regulatory approaches as necessary for enabling a modern energy infrastructure. Traditional regulatory approaches have supported a rigorous evaluation of investments to control costs of service provision. However, utilities and

regulators alike note that these traditional approaches are not designed to foster grid evolution. A future grid characterized by greater intelligence, two-way flow of information and electricity, technological innovation, and high penetration of DERs requires changes to regulatory decision-making. PBR is one option to consider, as it enables utilities to earn incentives for achieving specific outcomes that will be essential to creating the grid of the future.

CORE CONCEPT

The idea of PBR represents an evolution from traditional utility regulation. Regulatory goals, utility earnings opportunities, capital investment incentives, and regulatory processes change to focus on performance. Table 1 below contrasts traditional and PBR frameworks.

Regulatory agencies establish PBR by creating links between regulated utility financial rewards (or penalties) and desired outcomes. These outcomes are tied to an index of performance in addition to, or in place of, the cost of providing services. PBR also can include other elements of regulatory reform, such as revenue decoupling and multi-year forward-looking rate plans. Used together, these changes to cost-of-service regulation

can better align regulated earnings with desired outcomes.

PBR frameworks can also accelerate the way regulation reacts to market dynamics. Traditional regulatory processes can lag industry developments. This regulatory lag may unintentionally limit economic growth potential, slow technological advances and deployment, and negatively impact utility financial performance.

There is no one-size-fits-all solution for successful PBR deployment. Nevertheless, experience suggests that the following basic framework can be used to help policymakers and utilities design and implement changes that best fit their specific needs and circumstances.

Table 1 – Core PBR Concepts Compared to Traditional Regulation

	Traditional Regulation (Cost of Service)	Performance-based Regulation
Goals	Focus on reliability, affordability, adequacy of highly centralized electricity delivery systems. Consumers are protected from monopolistic power through reasonable rates and careful regulatory oversight.	Focus on traditional regulatory goals, as well as specific outcomes defined by policymakers, utilities, and stakeholders. Consumers are ensured reliable services. Facilitates opportunities for customer and third-party value creation and innovation.
Incentives for Utilities	Revenues are earned through recovered costs. Regulators approve costs, which are embedded in basic rates, often based on per-unit (volumetric) energy usage. The utility is incentivized to increase usage to drive up revenues.	Revenues are earned through a variety of rates and programs. Incentives are designed, communicated, and evaluated. Rates are designed to vary for value propositions to facilitate reliable services and technology deployment.
Earnings	Regulators evaluate prudent cost of expenditures for services, with the level of capital expenditure primarily driving earnings.	Utilities optimize total expenditures (capital and operating) and regulators reward valued outcomes. Regulated earnings are adjusted (up or down) based on performance against specific metrics.
Time Scale	Short-term focus on cost minimization, with a traditional long-term capital planning process.	Balanced focus on short-term cost minimization/near-term grid reliability investments and longer-term investment in future grid architecture, improving performance and achieving public policy goals.

IMPLEMENTING PBR

ESTABLISHING AUTHORITY TO IMPLEMENT PBR. When evaluating PBR, stakeholders must operate within the jurisdiction’s unique circumstances, including legal, institutional, utility, and financial market considerations. In many states, the utility regulator is uniquely positioned, and has statutory authority, to act related to PBR objectives. However, it must be clear which governmental entity has authority to define

what PBR means for the state. This includes a clear ability to act on utility incentives, including valued outcomes. Incentives that align utility revenues and cost recovery with effective performance encourage utilities to invest in a wider array of programs and technologies than they might otherwise consider under existing cost-of-service regulation. When designed appropriately, PBR may provide stability in rates and costs while

facilitating innovation in energy services and technologies and improving performance.

Case Study from Illinois' Smart Grid Act

In October 2011, Illinois passed the Energy Infrastructure Modernization Act (EIMA), which became law as Public Act 097-0616.⁵ As part of the broader act, the legislation required Commonwealth Edison and Ameren Illinois to file multi-year metrics to achieve performance goals over a 10-year horizon. This requirement ultimately led to the establishment of tracking and performance measurement on an array of categories, including reliability indices, peak demand reductions, renewable energy adoption, greenhouse gas reductions, reductions in estimated bills, and the adoption of new smart grid technologies.

It is important to identify opportunities and limitations that may impact a PBR framework. Many states have strong foundations that can serve as a basis for establishing PBR. For example, many state regulatory commissions already have authority to connect outcomes (e.g., performance on reliability indices, customer satisfaction metrics, or demand-side management goals) to utility financial opportunities. However, there may be authority that is limited, requiring either scoping a few areas of PBR, or seeking additional authority from lawmakers to pursue additional areas.

STAKEHOLDER ENGAGEMENT.

Stakeholder input in defining outcomes is crucial to PBR success. To increase transparency and stakeholder involvement, regulatory processes should ensure

stakeholders are part of establishing the critical aspects of PBR plans – such as setting performance targets and incentives. Utilities might understandably try to set easily achievable targets, whereas a regulatory body or other stakeholders may argue for targets that seemed unachievable. Engaging in a collaborative process, with the overarching policy objectives guiding the discussion, is more likely to result in a set of targets and incentives that will promote success and achieve meaningful outcomes.

For example, in Massachusetts, utility-sponsored energy efficiency programs have a strong performance component. An independent Energy Efficiency Advisory Council, made up of a variety of stakeholders, helps set energy efficiency targets and the associated incentive levels. Although the Massachusetts program falls short of a full PBR framework that would apply to a wider range of utility activities, it provides useful real-world experience with a successful program that is large, is embraced by the state's utilities, and combines PBR principles with other complementary policies (such as revenue decoupling).

DEFINING PERFORMANCE.

To implement PBR, legislators, regulators, and stakeholders should work together to define, prioritize, and incentivize desired performance. Performance objectives may be specific to a given jurisdiction. Examples of broad categories of performance include customer empowerment, operational reliability and efficiency, environmental sustainability, and market innovation. Specific metrics that can assess performance across these categories

are then defined (see *Establishing Metrics and Incentives* below).

The level of incentive is another important consideration. For PBR to be successful, incentives must be large enough to have the desired effect on utility behavior, but capped to protect consumers. In the UK, where they have implemented a comprehensive PBR framework,⁶ incentive levels are relatively large (+/- 300 basis points) but subject to an overall revenue cap, which prevents the utility from “gold plating” investments to drive up earnings without providing incremental benefits to customers. In New York State, which recently implemented a more modest version of PBR as an overlay to cost-of-service regulation, incentives are limited to a maximum of 100 basis points (positive only), but without a revenue cap. In situations where there is no revenue cap, we recommend converting incentives from basis-point adders to an absolute dollar figure, to avoid the situation where the utility may seek to drive up its rate-base investments to increase profits from PBR. For example, in Massachusetts, the incentive levels within its energy efficiency program are set at specific dollar amounts for specific levels of achievement.

ESTABLISHING METRICS AND INCENTIVES.

Generally, performance targets and metrics should be designed around the most important, forward-looking assumptions that impact the business case of a proposed utility investment. Although metric categories should be similar for all utilities in a jurisdiction, actual targets can vary from utility to utility to reflect differences in the customer base, system condition, or other factors.

While each jurisdiction should develop metrics most relevant to its goals, below are examples of specific metrics that are consistent with the evolving nature of the electricity system.

- ◎ **Reliability:** SAIDI⁷, SAIFI⁸, or other indices, if not already subject to performance requirements.
- ◎ **Data access:** Consumer access to standardized and actionable energy consumption data; third-party access to system data.
- ◎ **Energy efficiency:** Quantifiable reductions in total electricity usage.
- ◎ **Peak load reduction:** Targeted demand reductions during peak periods – a primary driver of utility costs.
- ◎ **Third-party resource deployment:** Distributed energy resource deployments by third parties (including on behalf of customers).
- ◎ **Interconnection:** Volume and processing speed of filling requests to connect resources to the electricity system.

PLANNING IN THE PBR CONTEXT.

Incentives are provided when a utility achieves certain goals (outputs); however, these new output incentives need to be considered in the context of the input incentives under which utilities currently operate. Broadly, output incentives are rewards for achieving certain outcomes, which are the result of a combination of investments, management, and operational decisions (and potentially the decisions of customers and other actors), while

input incentives focus on rewarding the capital invested in certain types of assets. When it comes to investments, utilities have short, medium, and long-term considerations. PBR should not lead utilities to focus on short-term gains at the expense of future performance. Any form of PBR must therefore include planning that provides insight on the impacts of the inputs over all time frames. An important foundation for effective PBR is thus a planning process that can show the reasonable alternatives for various investment and operating choices. This enables effective target-setting against the metrics developed in the PBR framework.

OPTIMIZING BETWEEN CAPITAL AND OPERATING EXPENSES.

One goal of a PBR framework is to put operating expenses on a more equal footing with capital investments, particularly when non-capital spending can provide a superior solution.⁹ This could be, for example, in procuring load reductions from customers and third parties deploying DER in lieu of a traditional distribution infrastructure upgrade. Another example could be incentivizing permanent peak reduction with targeted energy efficiency investments by building owners that help with near-term operational needs. Under a PBR framework, which does not just reward utilities for capital investment, utilities look at a broader array of potential solutions knowing that those based on operating expenses (e.g., contracts for demand response services, administration of energy efficiency programs) also provide earnings opportunities. Furthermore, incentives and rates could be

adjusted regularly pursuant to a review of utility performance and service quality metrics.

PRIORITIZING METRICS AND LEARNING.

The foregoing discussion suggests that there are many potential metrics from which to choose. Thus, some prioritization is necessary to make the implementation of PBR manageable. Regulators and other stakeholders should focus performance objectives where there is most need for improvement, where there are opportunities to pursue regulatory priorities, and where there is opportunity for change.

It is important to provide utilities with a reasonable set of initial metrics to gain experience with PBR. Experience in other states with PBR suggests beginning with a few, clear metrics.¹⁰ While metrics should obviously be aligned with regulatory policy priorities, we suggest two other basic criteria in developing a recommended list of initial metrics. These are (i) the ability for near-term implementation and (ii) the ability of individual metrics to inform multiple areas of performance within the broad categories of interest.

COMPLEMENTARY POLICIES.

When considering PBR, regulators and policymakers should consider various complementary policies that can make PBR more effective. These are generally targeted at countering the utility bias toward increasing capital investment, which can be an obstacle in making a shift toward rewarding performance. These include:

- ⦿ **Revenue decoupling**, which removes the disincentive for utilities to reduce volumetric sales.
- ⦿ **Multi-year forward looking rate plans**, in which base rates are set based on an approved multi-year investment plan, but are reconciled annually with actual investment.
- ⦿ **Comprehensive benefit-cost analysis**, which is used as a basis for developing multi-year rate plans.

CONCLUSION

PBR offers the potential to achieve policy objectives and improve public welfare while also retooling the utility business model for success in meeting those objectives. Experience shows that, with thoughtful design processes, rewarding performance can work well. Implementing PBR in each jurisdiction needs to be considered in the context of a utility system that is becoming increasingly complex. This suggests that a move toward PBR should also involve considerations of

adjustment to the regulatory process as a whole. This should include greater involvement early on by various stakeholders that will ultimately play an integral role in the utility being able to meet its performance targets.

To support PBR as described in this issue brief, utilities and regulators will also need to agree on a form of advanced planning that can better identify the benefits that come from all advanced technologies.
